r = 7

We know that for median of medians once selected half of the arrays will have at least 4 elements smaller than the median:

$4 \bullet \left(\frac{1}{2} \bullet \frac{n}{7}\right) = \frac{2n}{7}$

The worst case is then if the actual median is in the other portion

$n - \frac{2n}{7} = \frac{5n}{7}$

And the problem is divided into sub arrays with 7 elements is

$\frac{n}{7}$

$T(n) \le T\left(\frac{n}{7}\right) + T\left(\frac{5n}{7}\right) + O(n)$
